$$i \frac{2}{t} + \frac{\partial^2 x}{\partial x^2} - V(x) x = 0$$
 $(t = 1, m = \frac{1}{2})$

Implicit first order in time approximation:

$$j \frac{2^{n+1} - 2^n}{\Delta t} = - \frac{2^{n+1} - 2^{n+1} + 2^{n+1}}{\Delta x^2} + V_i \gamma_i^{n+1}$$

Unconditionally stable, but not unitary, ie.

$$\int_{-\infty}^{\infty} |y|^2 dx = 1$$

is not fulfilled.

To obtain a unitary solution, we consider $i\frac{\partial 4}{\partial x} = 47 \qquad , \qquad H = -\frac{\partial^2}{\partial x^2} + V(x)$

Formal solution $\psi(x,t) = e^{-iHt} \chi(x,t) defined by$ power series of the Operator.

(stable) implicit approx:
$$7^{4+1} = \frac{1}{1+jHAt} 7^{4}$$

26.1.16

In fact
$$1-j\Delta tH \approx e$$
 and $\frac{1}{1+jH\Delta t} \approx 1-jH\Delta t + O(\Delta t')$

are just two approximations which are first order.

A second order approximation is

$$e^{-j\Delta t H} \simeq \frac{1 - \frac{1}{2}jH\Delta t}{1 + \frac{1}{2}jH\Delta t}$$

which gives (starting from 2(x, At) = e 7(x,0)

Replacing H by its finite-difference form we obtain a complex tri-diagonal system.

$$= \frac{7}{3} + \frac{j \Delta t}{2 \Delta x^{2}} \left[\frac{7}{1+1} - 2\frac{7}{1+1} + \frac{7}{1+1} - j \frac{\Delta t}{2} \frac{V}{2}, \frac{7}{1+1} \right]$$

$$=$$
 $A \vec{7}^{\mu + 1} = A^* \vec{7}^{\mu}$

$$A = \begin{pmatrix} d_{0} & a & 0 & 0 \\ a & d_{1} & a & 0 \\ 0 & a & d_{2} & a \\ 0 & \dots & 0 & a & d_{N-1} \end{pmatrix}$$

$$\alpha = -j \frac{4t}{2} \frac{2x^2}{4x^2}$$

$$d_j = 1 + j \left(\frac{4t}{4x^2} + \frac{4t}{2} \right)$$

26.1.16

Splitting methods

Consider the linear ODE system

$$\frac{d\vec{y}}{dt} = A\vec{y}(t) \qquad \text{with} \qquad A = A_1 + A_2.$$

The formal solution is $\vec{y}(t) = e^{Att}\vec{y}(0)$.

If we can solve
$$\frac{d\vec{y}}{dt} = A_1 \vec{y}(t)$$
 and $\frac{d\vec{y}}{dt} = A_2 \vec{y}'(t)$

Le can approximate

$$\ddot{y}(\Delta t) = e^{A\Delta t} \ddot{y}(0) = e^{A_{\Delta} \Delta t} e^{A_{\Delta} \Delta t} \ddot{y}(0).$$

This is of first orde in It since

$$e^{A\Delta t} = \mathbf{I} + \Delta t \left(A_1 + A_2 \right) + \frac{1}{2} \Delta t^2 \left(A_1 + A_2 \right)^2 + \dots$$

$$e^{A_{2}\Delta t} = I + \Delta t (A_{1} + A_{2}) + \frac{1}{2} \Delta t^{2} (A_{1}^{2} + 2A_{2}A_{1} + A_{2}^{2}) + ...$$

$$\frac{1}{4}\left(e^{A\Delta t} - e^{A_2\Delta t} e^{A_1\Delta t}\right)\vec{g}(0) = \frac{1}{2}\Delta t \left(A_1A_2 - A_2A_1\right)\vec{g}(0) + O(\Delta t)$$
local error
$$[A_1A_2]$$

Thus, the method is first orde in time if A, and A. do not commute.

Up to here we always start with a full step with operator A_1 , then carry out one step with operator A_2 .

Retter accueracy can be obtained by alternating the first operator distrator in every half-step:

$$\ddot{y}(\Delta t) = \left(e^{\frac{1}{2}\Delta t A_{2}} e^{\frac{1}{2}\Delta t A_{1}}\right) \left(e^{\frac{1}{2}\Delta t A_{1}} e^{\frac{1}{2}\Delta t A_{2}}\right) \ddot{y}(0)$$

$$= e^{\frac{1}{2}\Delta t A_{2}} e^{\frac{1}{2}\Delta t A_{1}} e^{\frac{1}{2}\Delta t A_{2}} \ddot{y}(0) \qquad (Jtrang)$$

$$Splitting),$$

Strong splitting is second order in time.
These results hold for non-linear systems as well.

Split-step Focerie method for the noulinea Schrödinge Rq.

$$i4 + P4xx + Q|4|^24 = 0$$

 $i4 + 24 + N4 = 0$

$$i \psi_{t} + \psi_{t} \psi_{t} = 0 \psi_{t} = \mathbf{1} i \psi_{t} + \psi_{t} \psi_{t} = 0 \psi_{t} = \mathbf{1} i \psi_{t} \psi_{t} = 0 \psi_{t} = \psi_{t} = 0$$

$$\frac{d}{dt} |3|^2 = \frac{d}{dt} (32^*) = 3 \frac{d^2}{dt} + 3 \frac{d^2}{dt}$$

$$= 3 (-iQ|3|^2 3^*) + 3 (iQ|3|^2 3) = 0$$

$$= \frac{iQ | 4(4)|^2 \Delta t}{2(0)!^2 \Delta t}$$

$$= \frac{iQ | 4(4)|^2 \Delta t}{2(0)!^2 \Delta t}$$

$$= \frac{iQ | 4(0)|^2 \Delta t}{2(0)!^2 \Delta t}$$

For
$$\mathcal{L} = \partial_{xx}$$
: $i z_t = -P \partial_{xx} z_t$

$$\mathcal{Y}_{t} = +i P \frac{\partial^{2} \mathcal{Y}}{\partial x^{2}}$$

Forward-Fourier transf:
$$\frac{2}{4} = iP(-k^2)^{\frac{2}{4}}$$

$$2^{2}(\Delta t) = e^{-iPk^{2}\Delta t} 2^{2}(0) = \sum_{\text{Fourier-transl.}}^{\text{Fackword}} 2^{2}(\Delta t)$$
